

Various Commands For Linux:

Installing LAMP On Ubuntu

Install Apache

To start off we will install Apache.

```
sudo apt-get install apache2
```

testing Apache

<http://localhost>

Install PHP

```
sudo apt-get install php5 libapache2-mod-php5
```

```
sudo /etc/init.d/apache2 restart
```

Test PHP

```
sudo gedit /var/www/testphp.php
```

Step 2. Copy/Paste this line into the phptest file:

```
<?php phpinfo(); ?>
```

Step 3. Save and close the file.

Step 4. Now open your web browser and type the following into the web address:

`http://localhost/testphp.php`

Test PHP Page

Congrats you have now installed both Apache and PHP!

Install MySQL

```
sudo apt-get install mysql-server
```

```
mysql> SET PASSWORD FOR 'root'@'localhost' = PASSWORD('yourpassword');
```

(Make sure to change your password to a password of your choice.)

```
sudo apt-get install libapache2-mod-auth-mysql php5-mysql phpmyadmin
```

Try to access localhost/phpmyadmin and if it shows not found then follow steps below:

```
gksudo gedit /etc/php5/apache2/php.ini
```

add this line under include option

Include /etc/phpmyadmin/apache.conf

and finally restart apache.

```
sudo /etc/init.d/apache2 restart
```

Try to work it and if it doesn't go for below steps else not

Now we are going to have to uncomment the following line by taking out the semicolon (;).

Change this line:

```
extension=mysql.so
```

To look like this:

```
extension=mysql.so
```

Now just restart Apache and you are all set!

```
sudo /etc/init.d/apache2 restart
```

Install Xampp

Link :- <http://www.apachefriends.org/en/xampp-linux.html#372>

Step 3) Open terminal Go to downloads

```
type : sudo passwd root
for password put ntf12345
```

It will ask for new password and re enter password put same ntf12345
after that in downloads folder

```
Type command : su
Enter password : ntf12345
```

```
Type LS
cd downloads
Ls
chmod 755 x prees tab
./xampp-linux-1.8.2-2-installer.run
Now change permission of xampp file that is downloaded
```

Type : `chmod 755 xampp file name (Ex. ./xampp-linux-1.8.2-2-installer.run)`

after this :

Type: `./xampp file name (put x and then TAB it will take you to name)`

This will start xampp setup

Now you can start the server by `/opt/lampp/lampp start`

=====

The commands i used to solve the issue are as follows:

```
sudo opt/lampp/lampp stop
sudo /etc/init.d/apache2 stop
sudo /etc/init.d/mysql stop
```

You can also type instead:
sudo service apache2 stop
sudo service mysql stop

After that, we start again the lampp services:

sudo opt/lampp/lampp start

Now, there must be no problems while opening:

http://localhost
http://localhost/phpmyadmin

=====

Permission User

Type Who i am

sudo chown -R username:username /opt/lampp/htdocs

sudo gedit /opt/lampp/etc/httpd.conf

Restart Xampp

sudo /opt/lampp/lampp start

=====

change limit phpmyadmin import database

go file system /opt/lampp/etc/php.ini (open terminal & change limit) Find now this text & set limit,

memory_limit

post_max_size

upload_max_filesize

&

restart apache

sudo /opt/lampp/lampp restart

=====

Delete Any User in Ubuntu

Command :- sudo deluser (**User Name**)

=====

Xampp :- All Problem Solution

Link :- http://www.apachefriends.org/faq_linux.html

Remove Xampp

```
sudo /opt/lampp/lampp stop
```

```
sudo rm -rf /opt/lampp
```

Remove My SQL

```
sudo apt-get remove phpmyadmin
```

```
sudo apt-get remove mysql-server
```

```
sudo apt-get remove mysql-common
```

sudo fsck.ext4 -f /dev/sdaX

sudo touch/forcefsck

PageSpeed Insights

<http://developers.google.com/speed/pagespeed/insights/>

Install Ruby on Rails

Step One— Install Ruby with RVM

sudo apt-get update

Once that's done, we can start installing RVM, Ruby Version Manager. This is a great program that lets you use several versions of Ruby on one server; however, in this case, we will just use it to install the latest version of Ruby on the droplet.

If you do not have curl on your system, you can start by installing it:

sudo apt-get install curl

To install RVM, open terminal and type in this command:

```
\curl -L https://get.rvm.io | bash -s stable
```

After it is done installing, load RVM. You may first need to exit out of your shell session and start up a new one.

source ~/.rvm/scripts/rvm

In order to work, RVM has some of its own dependencies that need to be installed. To automatically install them:

rvm requirements

You may need to enter your root password to allow the installation of these dependencies. On occasion the zlib package may be reported as missing. The RVM page

Step Two— Install Ruby

Once you are using RVM, installing Ruby is easy.

rvm install ruby ruby -v 1.9.3

The latest ruby is now installed. However, since we accessed it through a program that has a variety of Ruby versions, we need to tell the system to use the version we just installed by default.

rvm use ruby --default

Check ruby version = >
ruby -v

Step Three— Install RubyGems

The next step makes sure that we have all the required components of Ruby on Rails. We can continue to use RVM to install gems; type this line into terminal.

rvm rubygems current

Step Four—Install Rails

Once everything is set up, it is time to install Rails.

To start, open terminal and type in:

gem install rails -v 3.2.13

Check rails version = >
rails -v

Install sublime text 2

wget <http://c758482.r82.cf2.rackcdn.com/Sublime\ Text\ 2.0.2.tar.bz2>

tar vxjf Sublime\ Text\ 2.0.2.tar.bz2

Install pg

Link : <http://www.devsnipr.com/postgresql-installation-and-settings-on-ubuntu-12-04/>

```
sudo apt-get install postgresql
sudo apt-get install postgresql libpq-dev
sudo su - postgres
```

- Change password of **postgres** user:
-

```
psql -d postgres -U postgres
```

```
psql (9.1.3) Type "help" for help
postgres=# alter user postgres with password 'YOUR_NEW_PASSWORD';
ALTER ROLE
postgres=# \q
#logout postgres user
logout
```

- Restart the PostgreSQL server:

sudo /etc/init.d/postgresql restart

This process may take a while, be patient with it. Once it finishes you will have Ruby on Rails installed on your droplet.

About Ruby on Rails

Ruby on Rails is an application stack that provides developers with a framework to quickly create a variety of web applications.

Rails can be installed on a virtual private server with a variety of packages, but it can also be download manually, from source. This tutorial will go over the manual installation.

Setup

The steps in this tutorial require the user to have root privileges. You can see how to set that up in the

Link :- [Initial Server Setup with Ubuntu](#)

in steps 3 and 4.

Step One—Download Ruby

Before you begin, make sure that your repository is up to date:

sudo apt-get update

Once the update finishes, we can start the ruby download:

Create a directory for the ruby download:

mkdir ~/downloads

Then switch into that directory:

```
cd ~/downloads
```

And begin downloading ruby:

```
sudo wget ftp://ftp.ruby-lang.org/pub/ruby/1.9/ruby-1.9.3-p0.tar.gz
```

Keep in mind that you can always access the latest version of ruby from the Ruby on Rails website:

Link :- <http://rubyonrails.org/download>

Once you have downloaded ruby, download the dependencies to your virtual server. These will help later to make the installation as smooth as possible.

```
sudo apt-get install build-essential openssl libreadline6 libreadline6-dev curl git-core zlib1g zlib1g-dev libssl-dev libyaml-dev libsqlite3-dev sqlite3 libxml2-dev libxslt-dev autoconf libc6-dev ncurses-dev automake libtool bison nodejs subversion
```

After the dependancies are installed on your VPS, unzip the ruby file:

```
tar xvfz ruby-1.9.3-p0.tar.gz
```

Once the process has completed, enter into the downloaded directory.

```
cd ruby-1.9.3-p0
```

Step Two—Install Ruby

Inside the Ruby directory we have to run the three standard commands to install the software. First:

```
./configure
```

"Configure" generates the make file and also checks that the server has all of the required dependancies. After that, still in the directory, you need to run the "make" command:

```
make
```

This may take a bit longer. Once it finishes, use make install:

```
sudo make install
```

Step Three—Install Gems

Once you have thoroughly unpacked the ruby code, the next step is to address the ruby gems. Since you installed the ruby package from the source, the gems should already be downloaded. However, you may need to update them:

```
sudo gem update --system
```

Step Four—Install Rails

After the gems are all up to date, you can complete the manual installation by setting up rails:

```
sudo gem install rails
```

With that, you have Ruby on Rails installed on your server.

Step Five—See Rails Online

After you have installed Ruby on Rails, you will be all set to start putting your ruby apps online.

To access the Ruby server, you simply need to make a new Ruby on Rails project:

```
rails new project_name
```

Enter into that directory:

```
cd project_name
```

And then turn on the rails server:

```
rails server
```

Step Six—RESULTS: Access Your Ruby Server

Once Ruby on Rails is installed, you can access your virtual private server by accessing your domain or IP address (ie. 12.34.56.789:3000).

The page should look like [this](#).

Excellent—you have now installed Ruby on Rails from source.

Install via the Package Manager(apt-get):

I know this already answered but you can simply just add to your packages:

For Sublime-Text-2:

```
sudo add-apt-repository ppa:webupd8team/sublime-text-2
```

```
sudo apt-get update
```

```
sudo apt-get install sublime-text
```

For Sublime-Text-3:

```
sudo add-apt-repository ppa:webupd8team/sublime-text-3
sudo apt-get update
sudo apt-get install sublime-text-installer
```

Android eclips plug in Link

Setup Link :- <https://developer.android.com/sdk/index.html?hl=sk>

plug in link :- <https://dl-ssl.google.com/android/eclipse/>

Do Not use this command. (Use Only Server)

Server Installation

=====

Server Git

Link :- <http://git-scm.com/download/linux>

```
apt-get install git
```

Server Ubuntu FTP Restart

```
sudo /etc/init.d/vsftpd restart
```

=====

Server vsftpd on Ubuntu 12.04

Link :- <https://www.digitalocean.com/community/tutorials/how-to-set-up-vsftpd-on-ubuntu-12-04>

install vsftpd on your virtual private server

command :-

```
sudo apt-get install vsftpd
```

```
sudo nano /etc/vsftpd.conf
```

The biggest change you need to make is to switch the Anonymous_enable from YES to NO:

```
anonymous_enable=NO
```

Prior to this change, vsftpd allowed anonymous, unidentified users to access the server's files. This is useful if you are seeking to distribute information widely, but may be considered a serious security issue in most other cases.

After that, uncomment the local_enable option, changing it to yes and, additionally, allow the user to write to the directory.

```
local_enable=YES
```

```
write_enable=YES
```

```
chroot_local_user=YES
```

Create a new directory within the user's home directory

```
mkdir /home/username/files
```

Change the ownership of that file to root

```
chown root:root /home/username
```

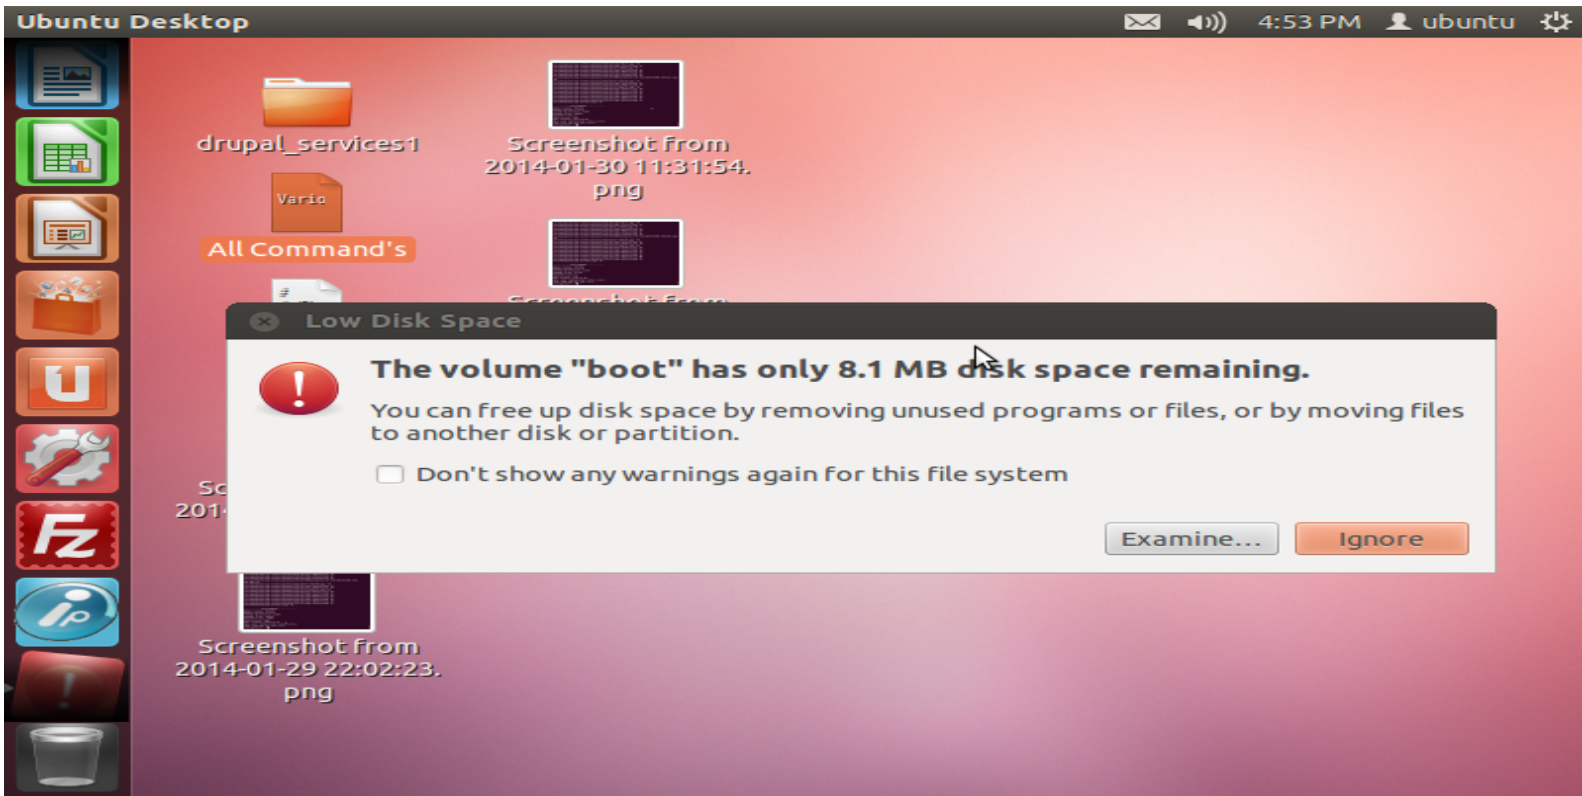

Make all necessary changes within the "files" subdirectory

Then, as always, restart:

```
sudo service vsftpd restart
```

=====

The Volume "boot" has only 8.1 MB free space remaining solution

dpkg-query -W -f='\${Package}\n' 'linux-image-*

Current use package
uname -r

Example :- **3.5.0-49-generic**

Note Do not remove current package

For Example look this **3.5.0-49-generic**

```
sudo apt-get autoremove linux-image-3.5.0-28-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-21-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-22-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-23-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-25-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-26-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-27-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-30-generic
```

```
sudo apt-get autoremove linux-image-3.8.0-31-generic
```

```
sudo apt-get update
```

```
*****
```

Putty not Connected Error : connection reset by peer

Solution :-

```
cd /etc
```

```
sudo mv ssh/ ssh.old/
```

```
sudo apt-get remove openssh-server openssh-client ssh-import-id
```

Watch the output and make sure it is uninstalling. Then install it again:

```
sudo apt-get install openssh-server openssh-client ssh-import-id
```

The installation process **should** generate new host key files, if not, check if you have removed/renamed the `/etc/ssh/` folder properly.

This is the sign when your problem is about to be solved:

```
Unpacking openssh-server (from .../openssh-server_1%3a5.9p1-5ubuntu1_amd64.deb) ...
Selecting previously unselected package ssh-import-id.
Unpacking ssh-import-id (from .../ssh-import-id_2.10-0ubuntu1_all.deb) ...
Processing triggers for ureadahead ...
ureadahead will be reprofiled on next reboot
Processing triggers for ufw ...
Processing triggers for man-db ...
Setting up openssh-server (1:5.9p1-5ubuntu1) ...
Creating SSH2 RSA key; this may take some time ...
Creating SSH2 DSA key; this may take some time ...
Creating SSH2 ECDSA key; this may take some time ...
ssh start/running, process 21733
Setting up ssh-import-id (2.10-0ubuntu1) ...
```

=====

Install EHCP web hosting cpanel on Ubuntu server

12.04/12.10/13.04/13.10/14.04

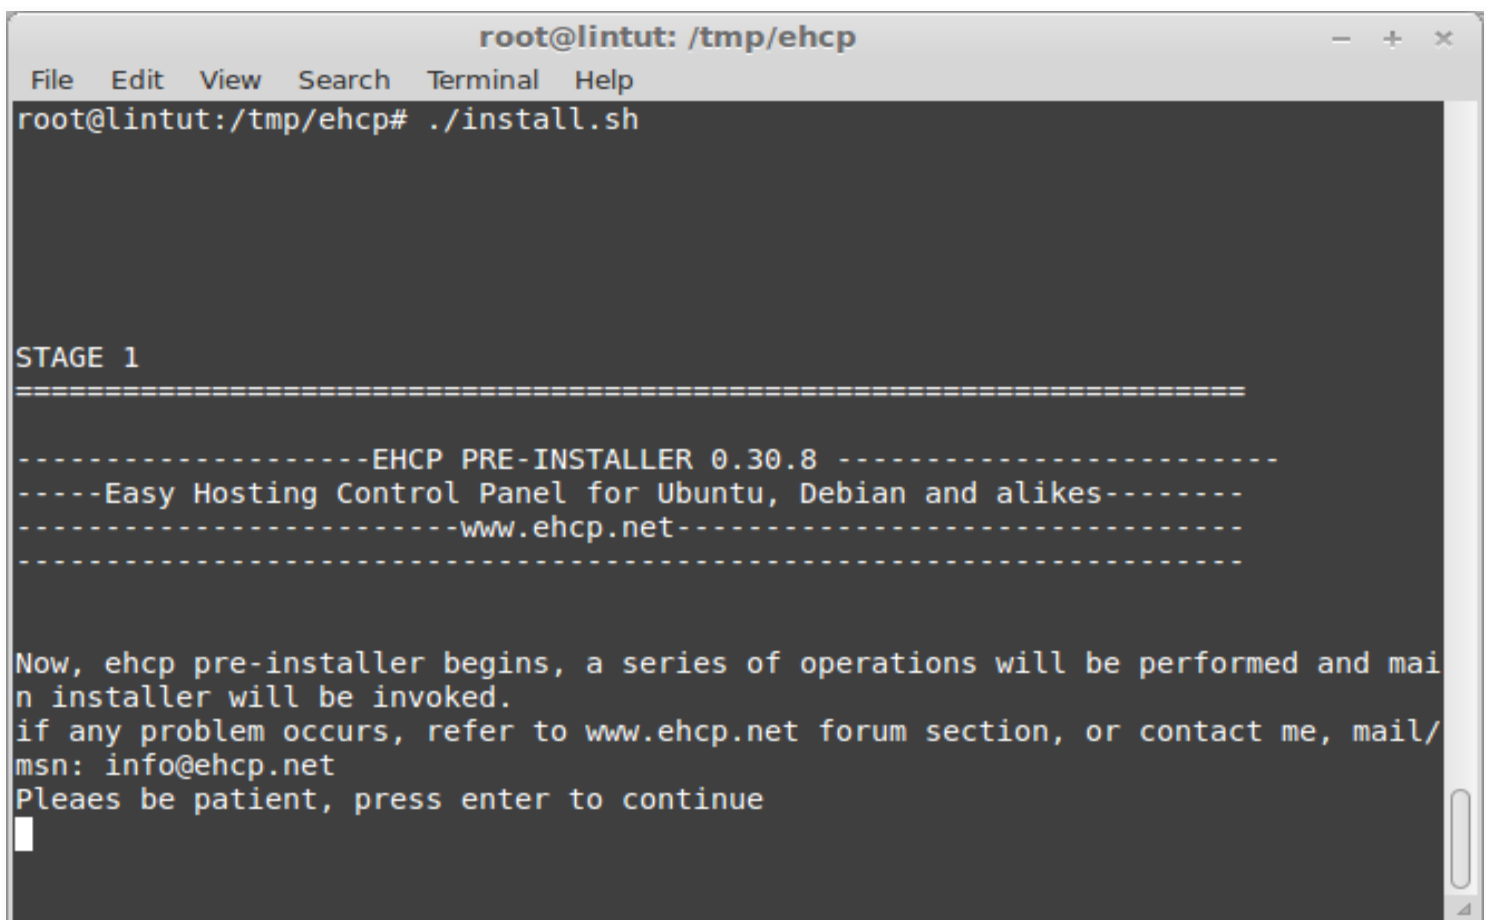

Link : - <http://lintut.com/install-ehcp-webhosting-cpanel-on-ubuntu-server/>

Commads : -

```
wget -O ehcp.tgz www.ehcp.net/ehcp\_latest.tgz  
tar -zxvf ehcp.tgz
```

Change to ehcp directory, then run *install.sh* script:

```
cd ehcp  
./install.sh
```

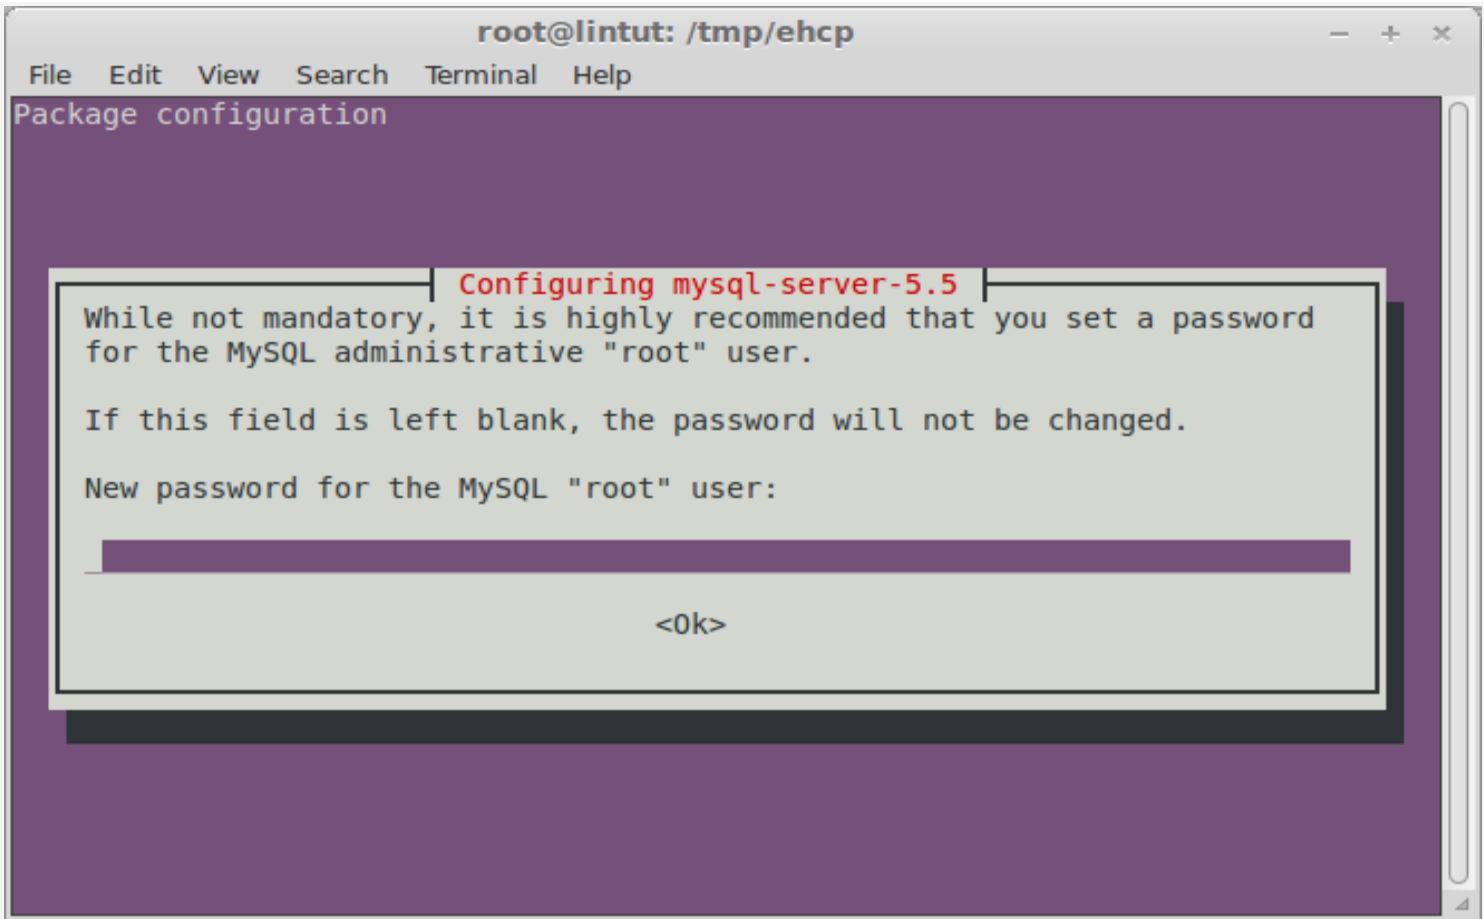

```
root@lintut: /tmp/ehcp  
File Edit View Search Terminal Help  
root@lintut:/tmp/ehcp# ./install.sh  
  
STAGE 1  
=====
```

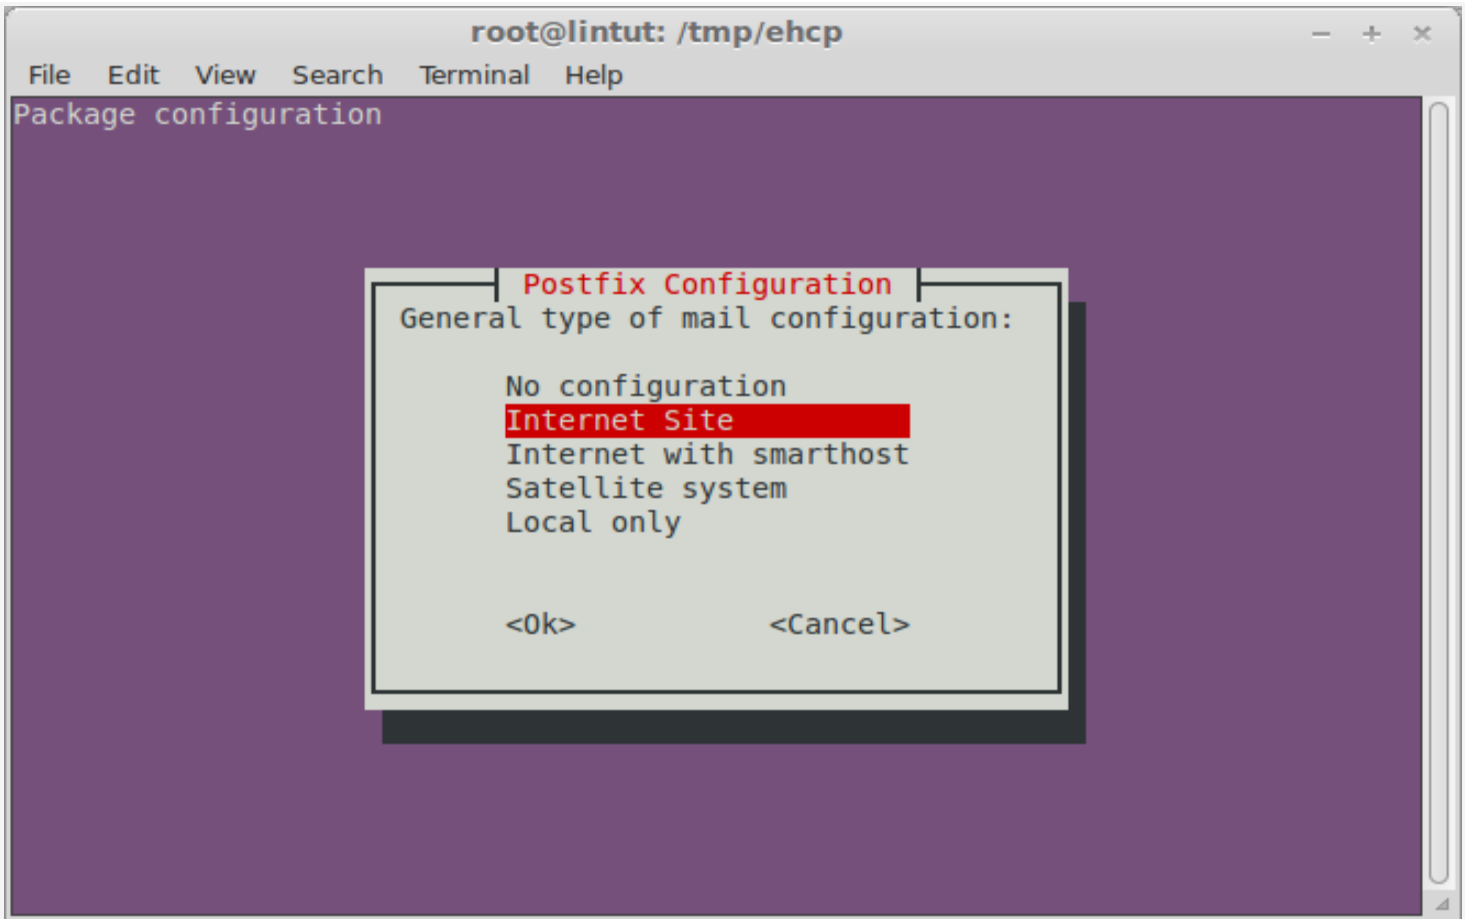

```
-----EHCP PRE-INSTALLER 0.30.8 -----  
-----Easy Hosting Control Panel for Ubuntu, Debian and alikes-----  
-----www.ehcp.net-----  
-----
```

```
Now, ehcp pre-installer begins, a series of operations will be performed and main installer will be invoked.  
if any problem occurs, refer to www.ehcp.net forum section, or contact me, mail/msn: info@ehcp.net  
Pleaes be patient, press enter to continue  
█
```

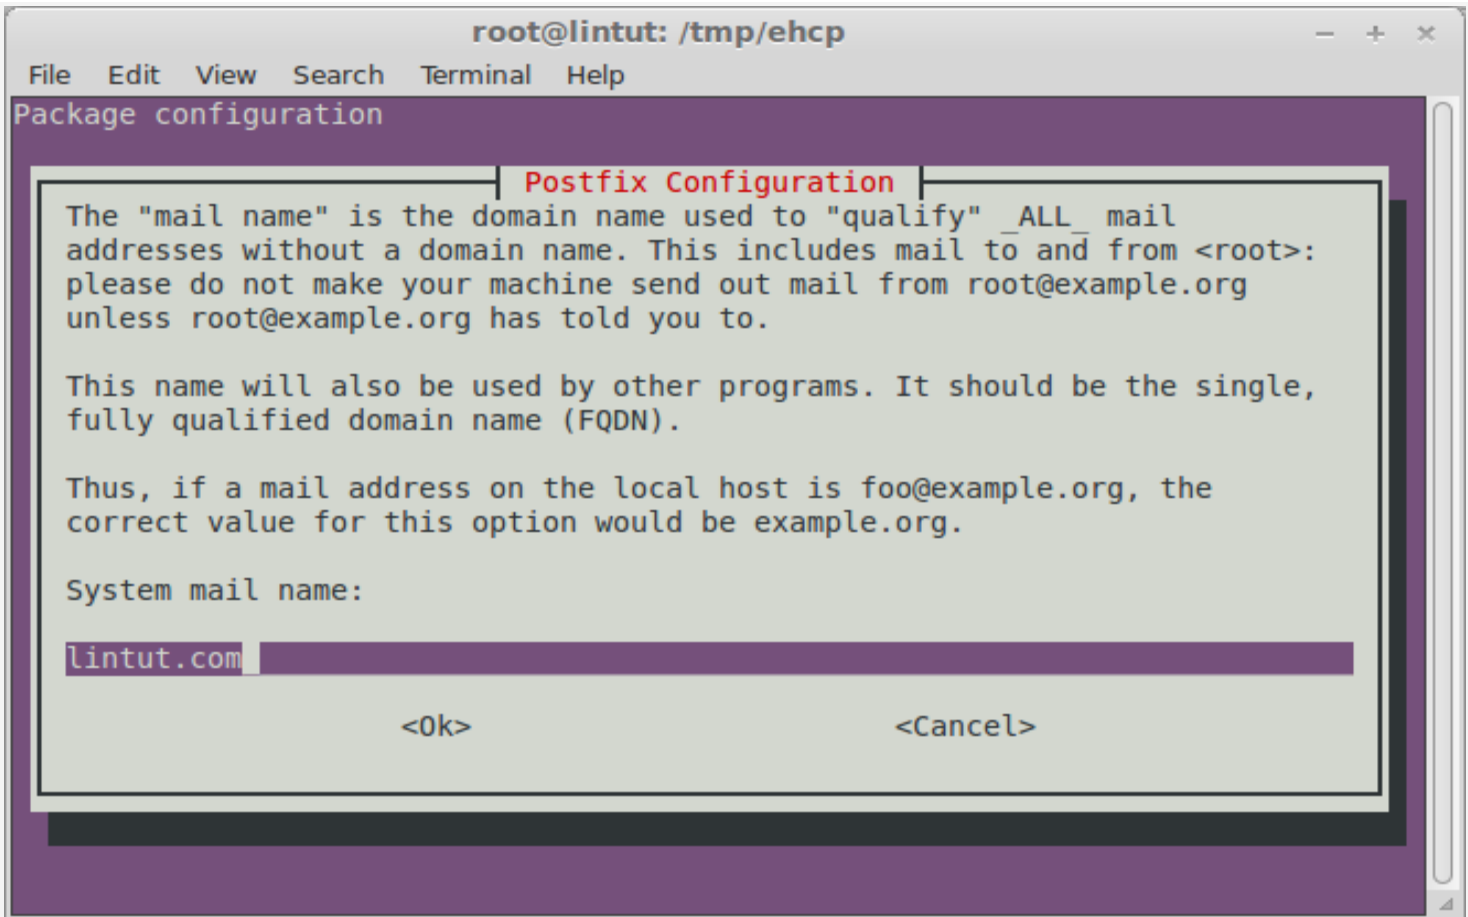

EHCP installation script install all needed packages including **Apache**, **MySQL**, **PHP**, **Postfix**.
It is highly, recommended you to set a **MySQL** 'root' password for **MySQL** administration.

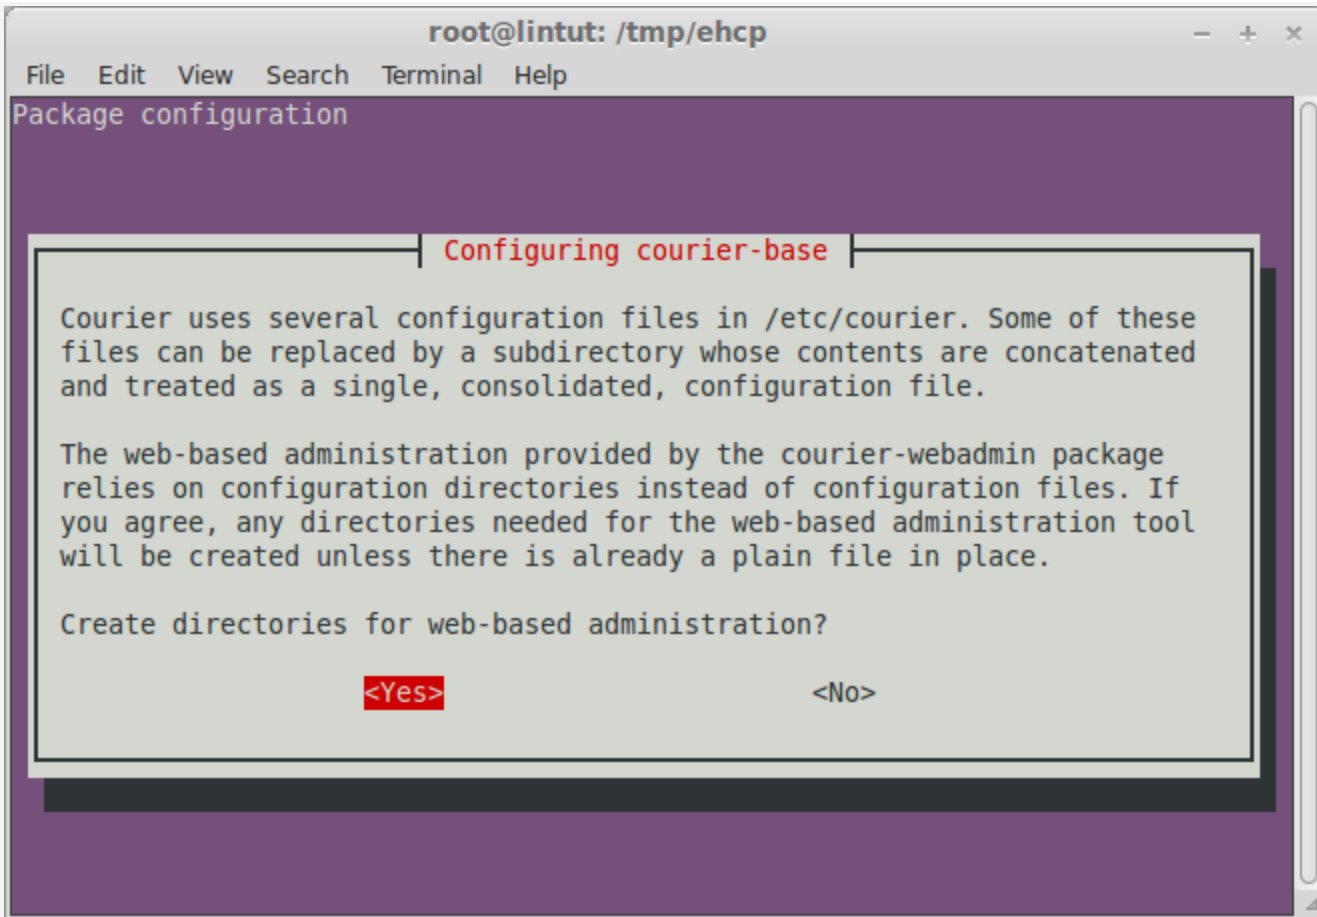

Now select the mail server which one is compatible to you. In my case I select "Internet Site".

Enter your mail domain name and Click OK.

Select 'Yes' to create web based directories.

Create SSL certificate for POP and IMAP. Click on 'Ok'.

root@lintut: /tmp/ehcp

File Edit View Search Terminal Help

Package configuration

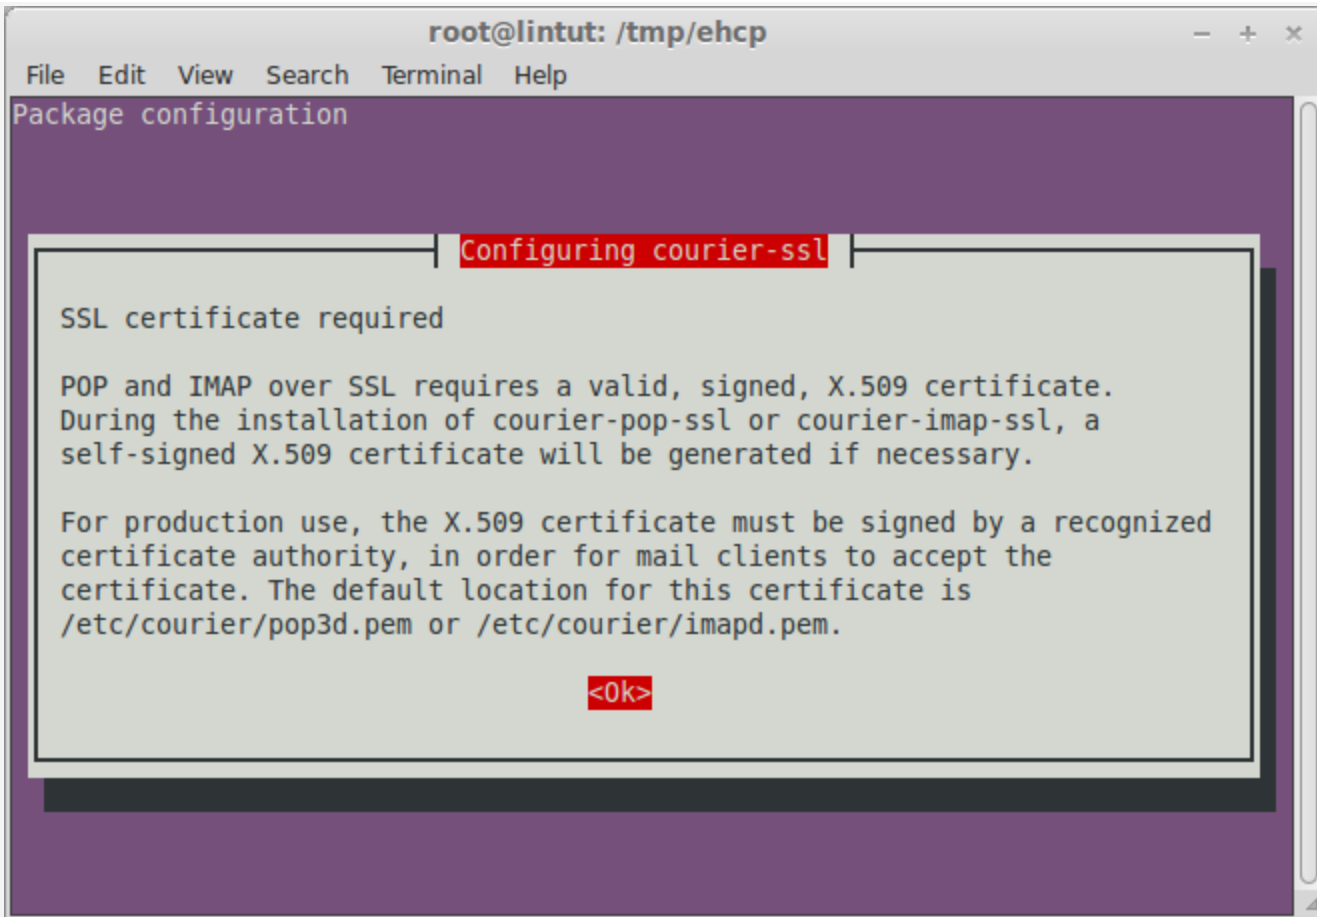

Configuring courier-ssl

SSL certificate required

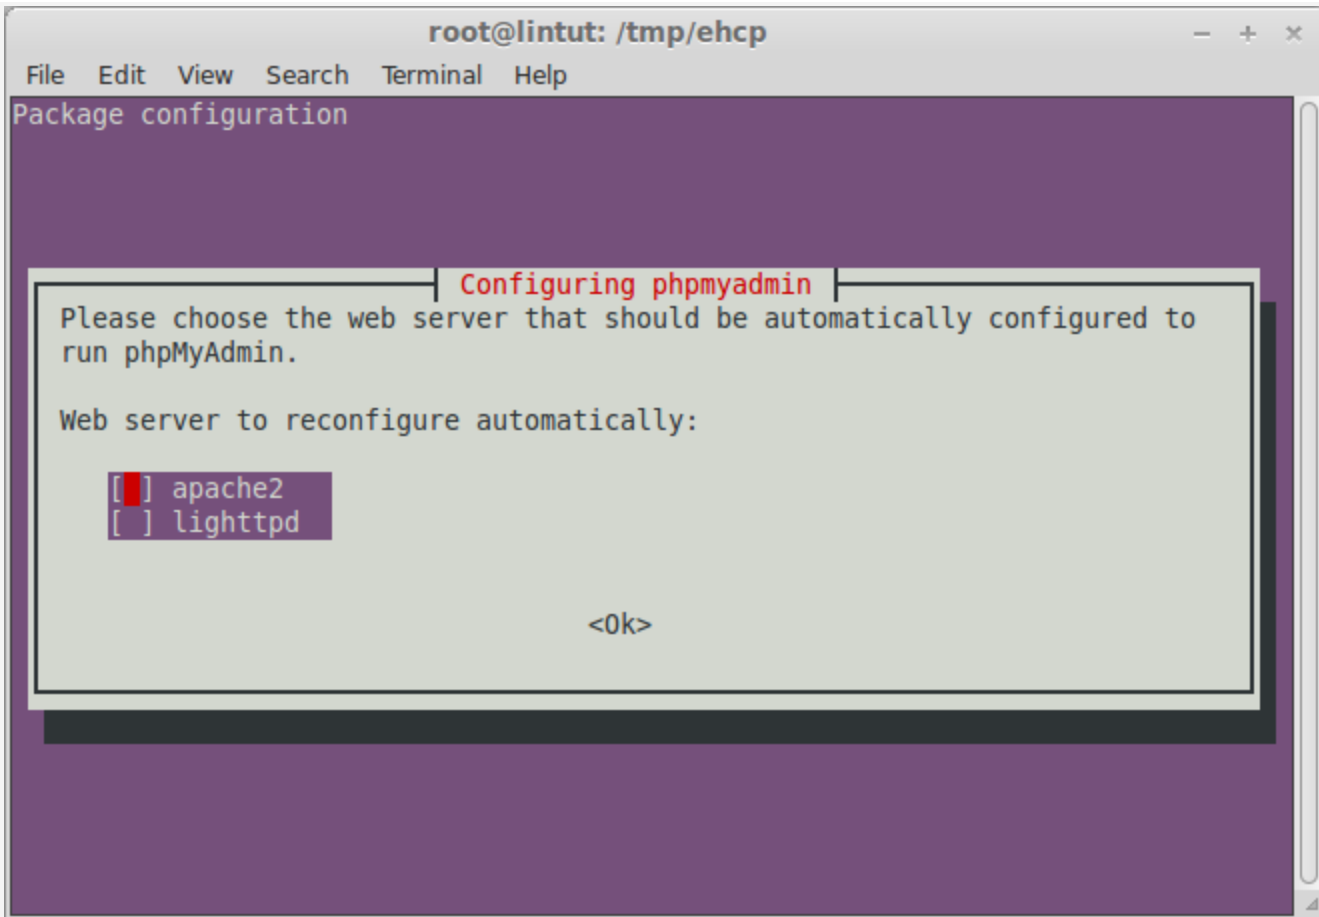

POP and IMAP over SSL requires a valid, signed, X.509 certificate. During the installation of courier-pop-ssl or courier-imap-ssl, a self-signed X.509 certificate will be generated if necessary.

For production use, the X.509 certificate must be signed by a recognized certificate authority, in order for mail clients to accept the certificate. The default location for this certificate is /etc/courier/pop3d.pem or /etc/courier/imapd.pem.

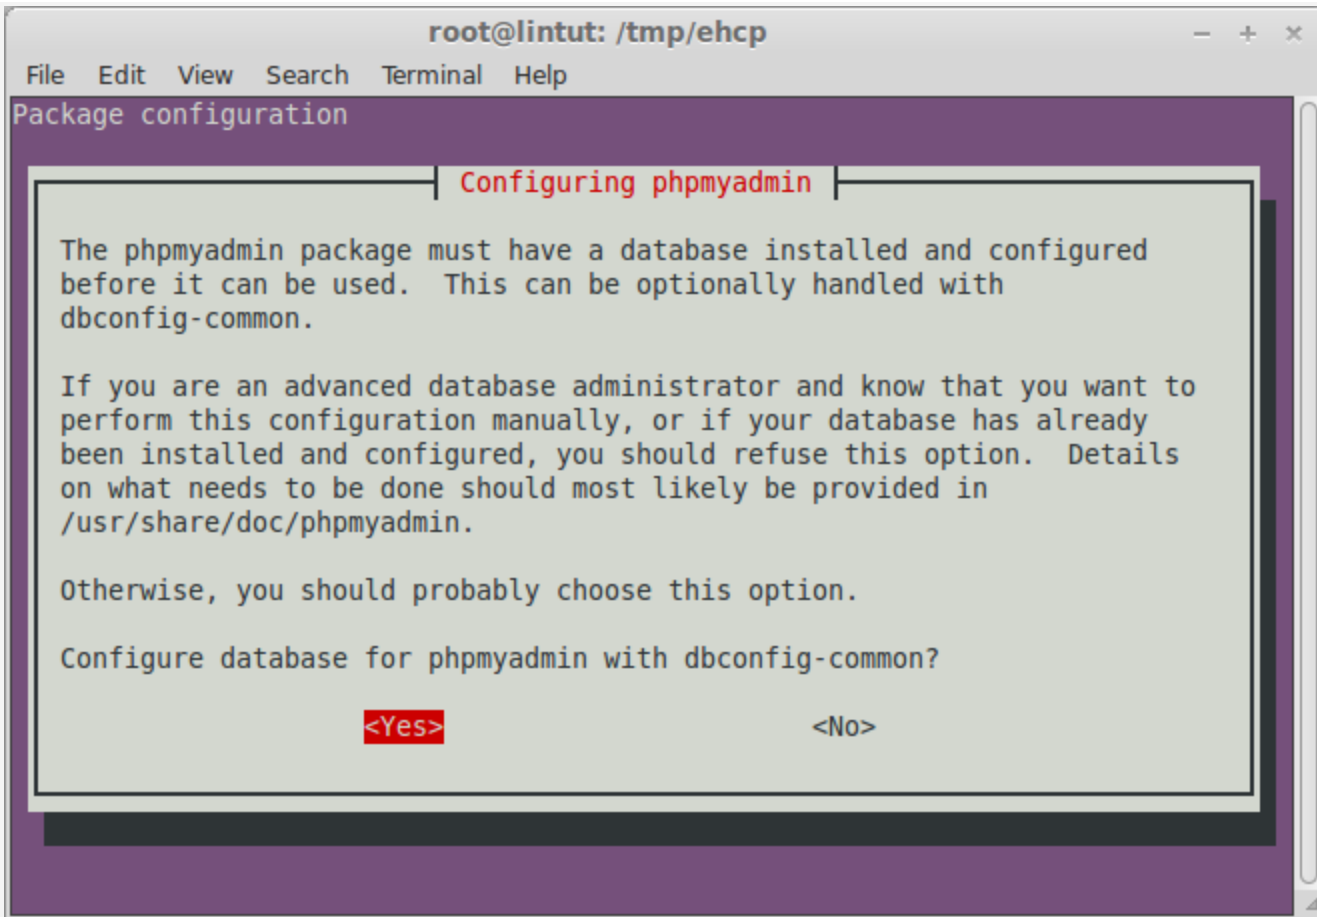

<Ok>

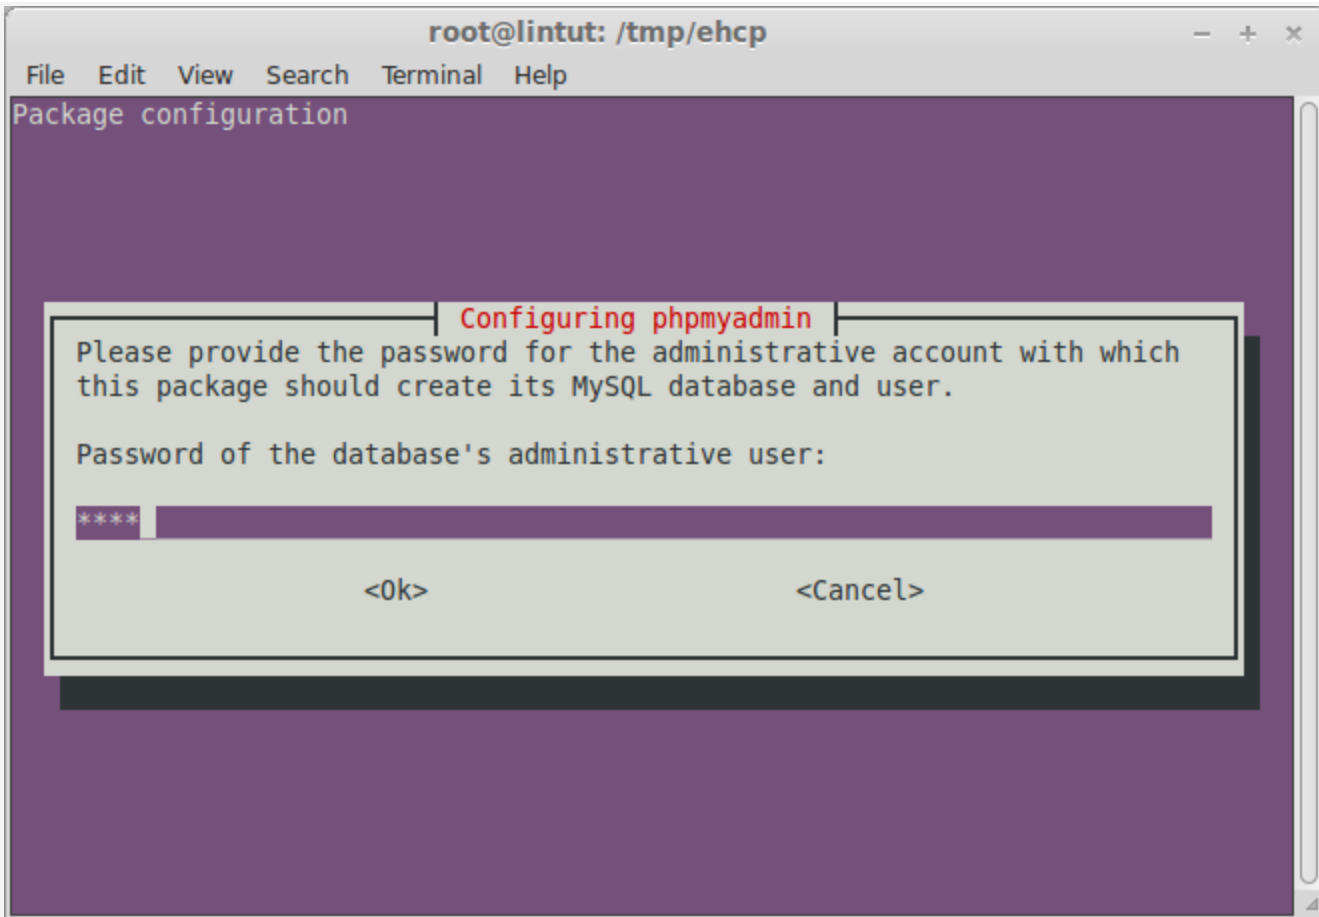

Please choose the web server that should be automatically configured to run phpMyAdmin.

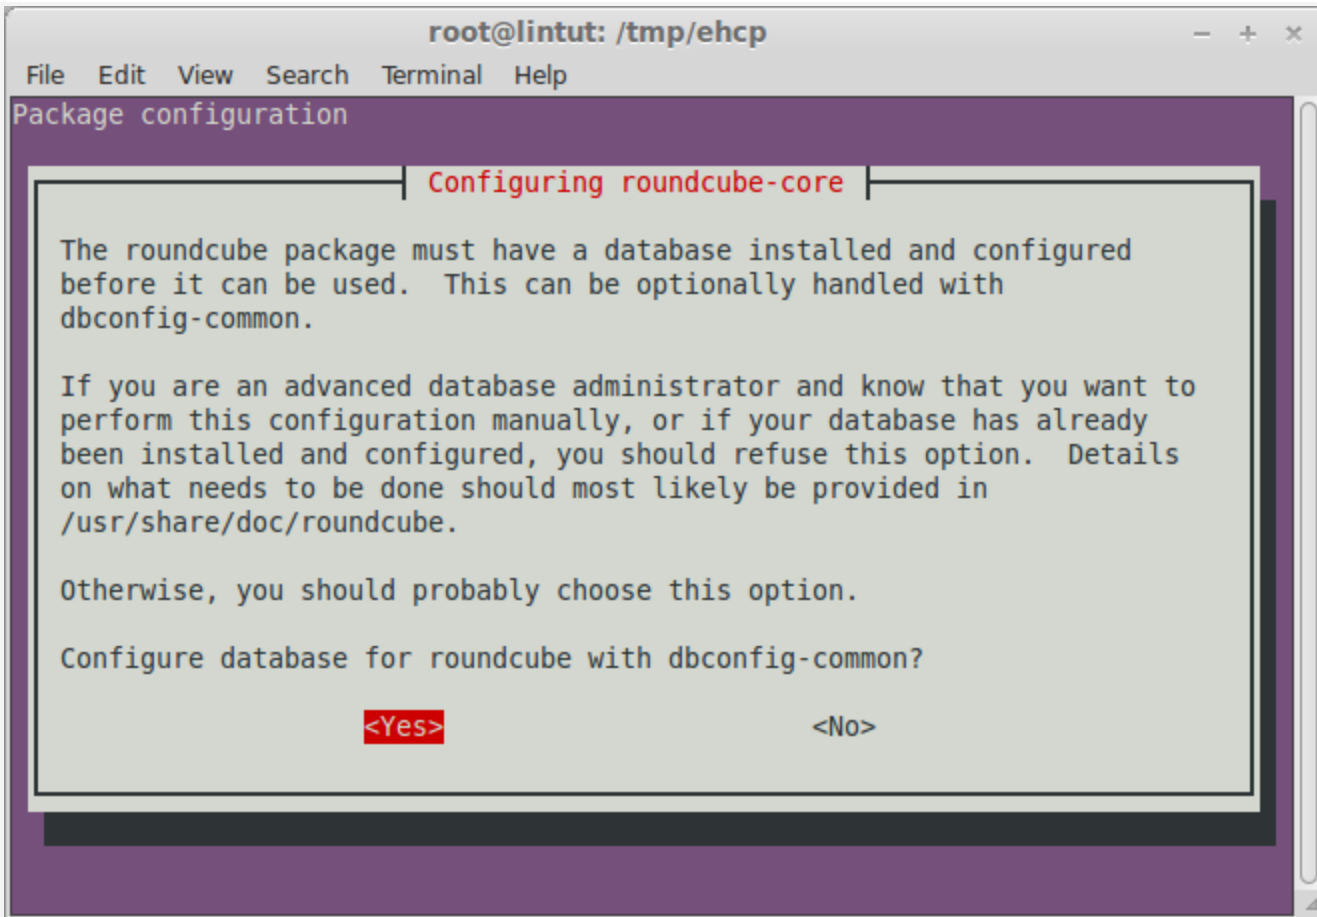

Configure phpMyAdmin database.

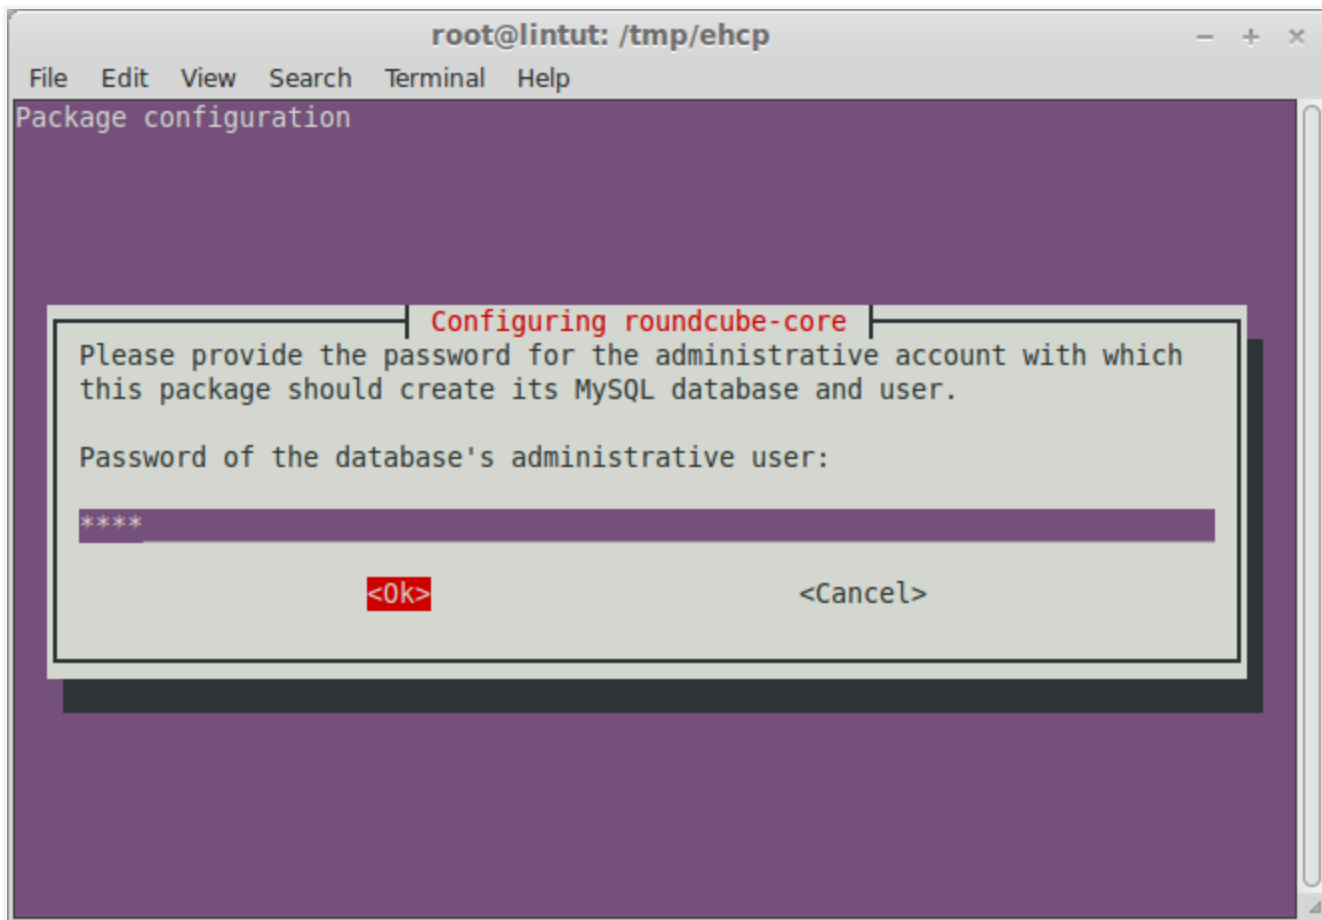

Specify the phpmyadmin database administrative user password.

Now configure the roundcube-core.

Please select the database type that used by roundcube.

Finished installation

```
root@lintut: /tmp/ehcp
File Edit View Search Terminal Help

-----
finished installation , bye !

now running ehcp daemon..

stopping ehcp..
stopping ehcpdaemon2.sh
stopping index.php daemon
stopping ehcp_daemon.py, python background server process
starting ehcp..
starting ehcp_daemon.py
root 32425 0.0 0.2 4792 1332 pts/0 S+ 11:22 0:00 /bin/bash /var/
www/new/ehcp/ehcpdaemon2.sh
ehcp run/restart complete..
ehcp : Finished all operations.. go to your panel at http://yourip/ now...
You have mail in /var/mail/root
root@lintut:/tmp/ehcp#
```

Now, navigate to the Web browser window and enter IP address of your server.

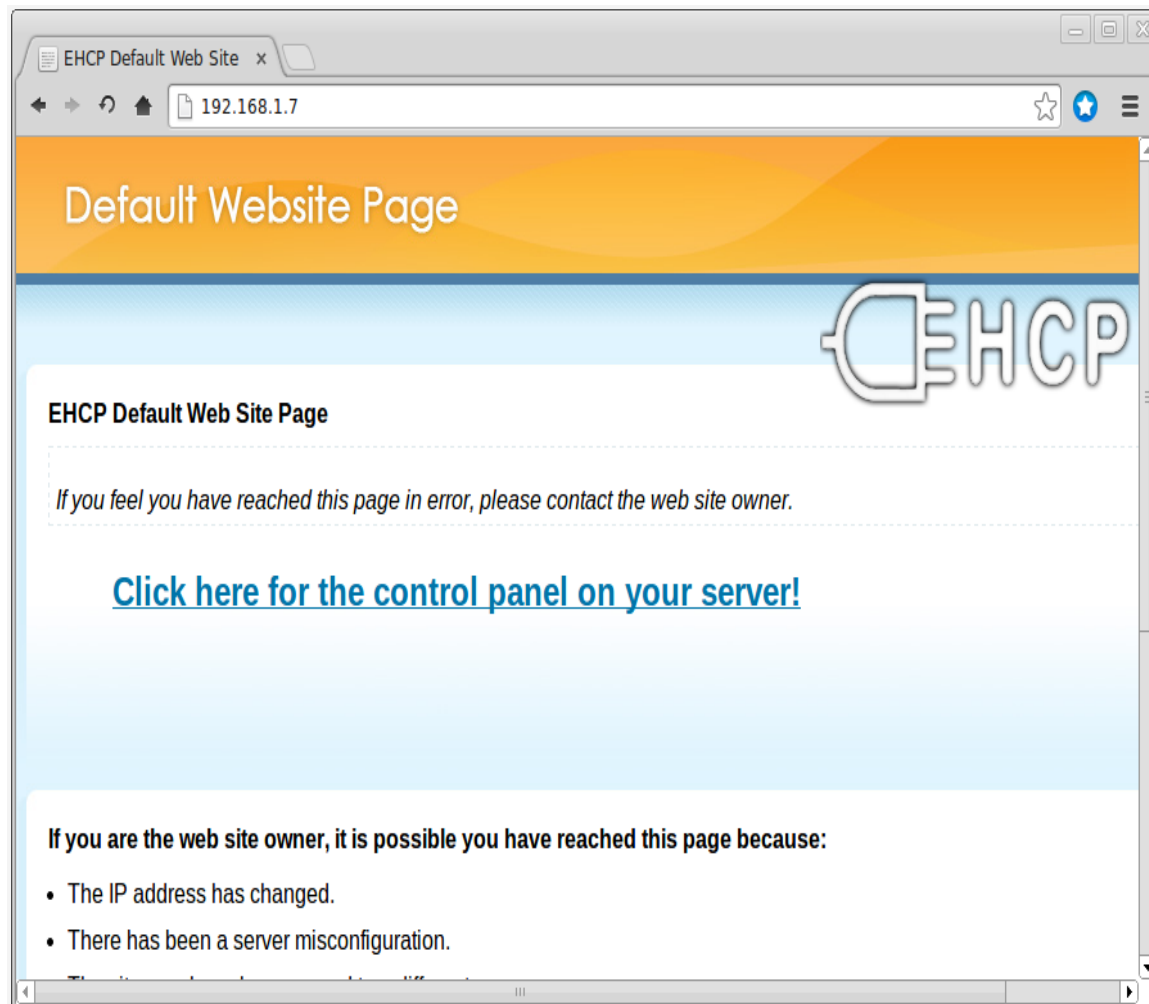

<http://youripaddress/>

<http://youripaddress/>

OR

<http://localhost>

Enter **ehcp** login details, default admin username is '**admin**' and default admin password is '**1234**'. If you've set new admin password during installation enter that password.
